TITLE : STATOR FOR MOTOR AND  
MANUFACTURE THEREOF

**ABSTRACT :** PROBLEM TO BE SOLVED: To improve the quality of a stator for a motor used for driving a ventilating fan, etc., and using a split core by securing a sufficient insulating distance between a winding and a stator core, without having to reduce the winding space of the winding.

**SOLUTION:** A stator for motor is constituted by attaching insulators 4, having the same shape to both sides of a T-shaped split core 1 via insulating films 2, and a recessed section 9 and a projecting section 10 are respectively provided at both ends of an internal wall section 7 which prevents the tilting of a winding wound around the insulator 4, together with a flange-like external wall section 6. In addition, a plurality of split cores 1, wound with windings 12, are joined to each other in the peripheral direction by engaging the recessed sections 9 of the cores 1 with the projecting sections 10 of their adjacent cores 1. A sufficient winding space can be secured for each winding 12, when the thickness of the internal wall section 7 is reduced, by making the insulating distance between the winding 12 near the internal wall section 7 and the core 1 to follow the creepage distance for insulation along the engaged surface.
